

# Kinetics and Thermodynamics of 7m MEA and 7m MEA/2m PZ Solutions

Ross Dugas, Marcus Hilliard and Gary Rochelle

Department of Chemical Engineering, The University of Texas at Austin

## INTRODUCTION

Aqueous amine absorption/stripping is currently the best technology to remove CO<sub>2</sub> from the flue gas of existing coal fired power plants. It is a tail end process that will not significantly disrupt the operation of the power plant. However, this technology is expensive and would require a significant portion of the plant's generated stream to power the regeneration system. One approach to lower capital and operating costs of the system involves using advanced amine solvents.

## OBJECTIVES

### Wetted Wall Column

- Measure the CO<sub>2</sub> reaction rate and equilibrium CO<sub>2</sub> partial pressure of 7m MEA and 7m MEA/2m PZ solutions over a wide range of CO<sub>2</sub> loading at both absorber and stripper conditions (40 – 100 °C).

### Closed-loop Stirred Reactor

- Measure CO<sub>2</sub> equilibrium partial pressure and amine volatility

## WHY 7m MEA/2m PZ?

- **Faster Rates**
  - Less Packing
  - Richer Solution
  - Lower Energy Requirements
- **Greater Capacity**
  - Lower Flow Rates
  - Smaller Heat Exchangers, Pumps

## EXPERIMENTAL APPARATUS

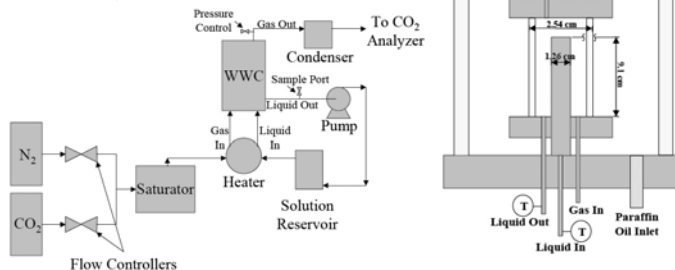

### Closed-loop Stirred Reactor

- Equilibrium CO<sub>2</sub> Partial Pressure, Amine Volatility
- 1 atm, 30-70 °C

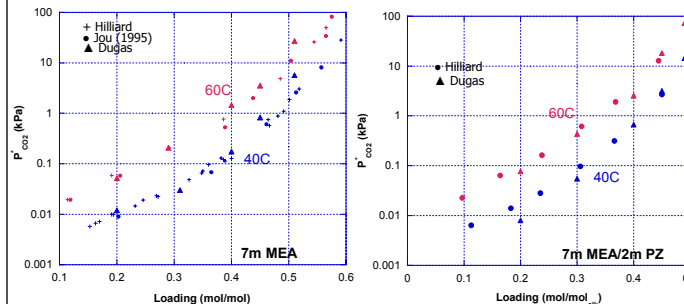

### Wetted Wall Column

- Kinetics, Equilibrium CO<sub>2</sub> Partial Pressure
- 30-100 °C, 1-7 atm

## THERMODYNAMIC RESULTS

- Hilliard, Jou and Dugas VLE data match well

- 45% Greater CO<sub>2</sub> Capacity for 7m MEA/2m PZ

## KINETIC RESULTS

- 7m MEA/2m PZ have faster rates than 7m MEA
- Rich end conditions (1000-5000 Pa) are most important

## CONCLUSIONS

- 7m MEA/2m PZ has a 45% greater CO<sub>2</sub> capacity than 7m MEA
- MEA and PZ volatility was successfully quantified
- 7m MEA/2m PZ shows faster rates than 7m MEA in the most important partial pressure range, 1000 to 5000 Pa.
